

# Tor Circuits

We want to hide metadata.

↳ Idea 1: route message through proxy  
! But now the proxy knows the recipient

↳ Idea 2: Enlist a bunch of intermediaries  
& build a circuit.

↳ choose among a set of volunteer relays  
& construct a circuit.

! So, the adversary will lose track of msgs  
once they enter this relay.

# Core communication piece in Tor:

"Cells" ← like TLS has packets, Tor has cells. It's just a name to call communication units

Types of "Cells":

→ Command Cells - Help to build/destroy circuits

→ Relay Cells - carry data

→ ...

All relays  $R$  have  
a public key  $pk_R$

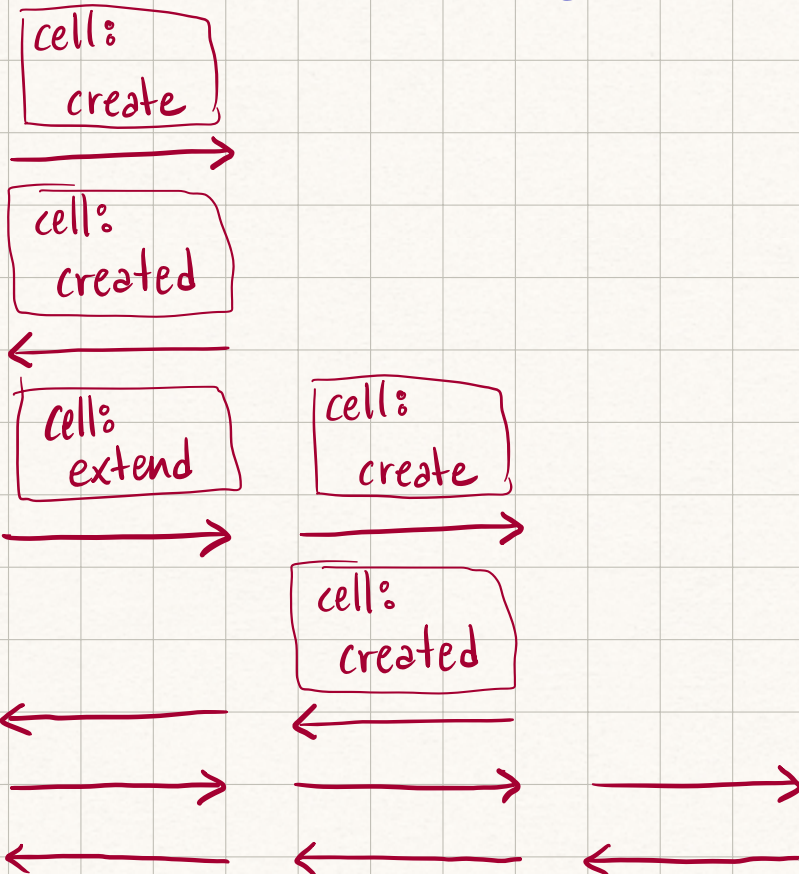

→ relays have existing  
TLS connections  
between them.

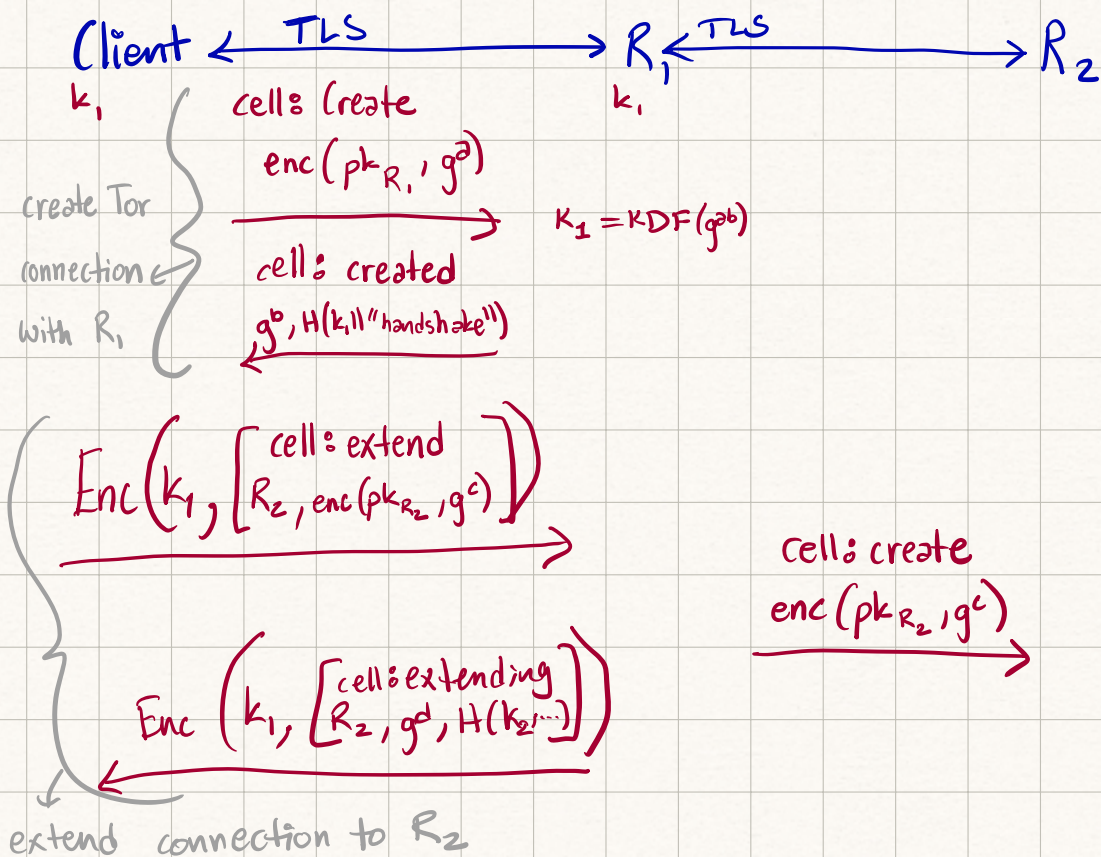

## Telescoping Connection

Client  $\longleftrightarrow$   $R_1$   $\longleftrightarrow$   $R_2$   $\longleftrightarrow$  Server

## Telescoping Connection Continued

# Onioning

Client  $\xleftrightarrow{\text{TLS}}$   $R_1$   $\xleftrightarrow{\text{TLS}}$   $R_2$   $\xleftrightarrow{\text{TLS}}$  Server

cell

Begin, Server IP, Server Port

The Client will send the following encryption to  $R_1$  that will be peeled back in layers. Hence the name onioning

①

Client

(create,  $c_1$  ||  $\text{Enc}_{k_1}(\text{Enc}_{k_2}(\text{cell}))$ )

$R_1$

identifier of circuit from Client to  $R_1$

②

$R_1$

(create,  $c_2$  ||  $\text{Enc}_{k_2}(\text{cell})$ )

$R_2$

① Look up  $c_1$  to get  $k_1$  &  $c_2$

② decrypt using  $k_1$

②  $R_2 \xleftarrow{\text{build TCP connection}} \text{Server}$

① Look up  $c_2$  to get  $k_2$

② decrypt using  $k_2$

---

$c_1 \parallel Enc_{k_1}(Enc_{k_2}(\text{cell})) \rightarrow c_2 \parallel Enc_{k_2}(\text{cell}) \rightarrow \text{cell}$
